

The background image shows two military vehicles in a desert environment. One vehicle is on the left, parked on a rocky bank with the number '25 NL' on its side. The other vehicle is in the foreground, partially submerged in a river, with 'ISAF' on its side. The scene is set in a dry, rocky landscape with sparse vegetation.

NEURO-SYMBOLIC MODELLING FOR OPERATIONAL DECISION SUPPORT

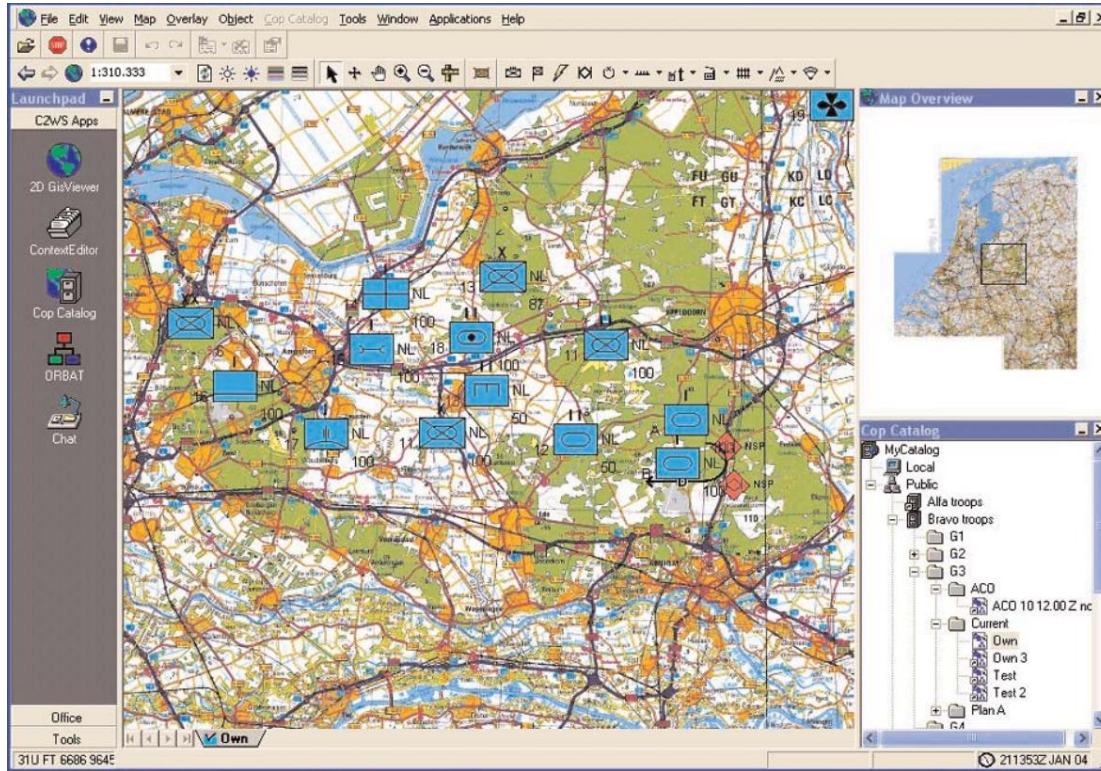

Jeroen Voogd, Patrick Hanckmann, Paolo de Heer, Jeroen van Lith

Little time available
Trustworthy results

REQUIREMENT: SUITABLE MODELS

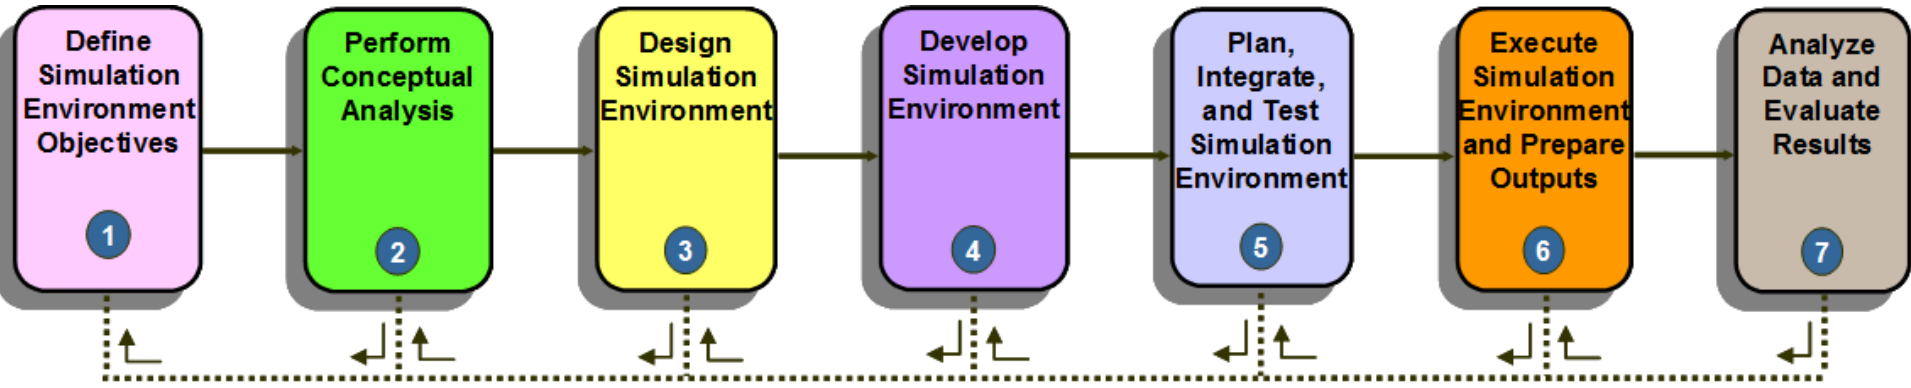

REQUIREMENT: SUITABLE MODELS

REQUIREMENT: SUITABLE MODELS

GOOD MODELS IN LITTLE TIME

- › Data + expert knowledge -> Situational Understanding (SU)
- › SU + commander's intent -> valid model

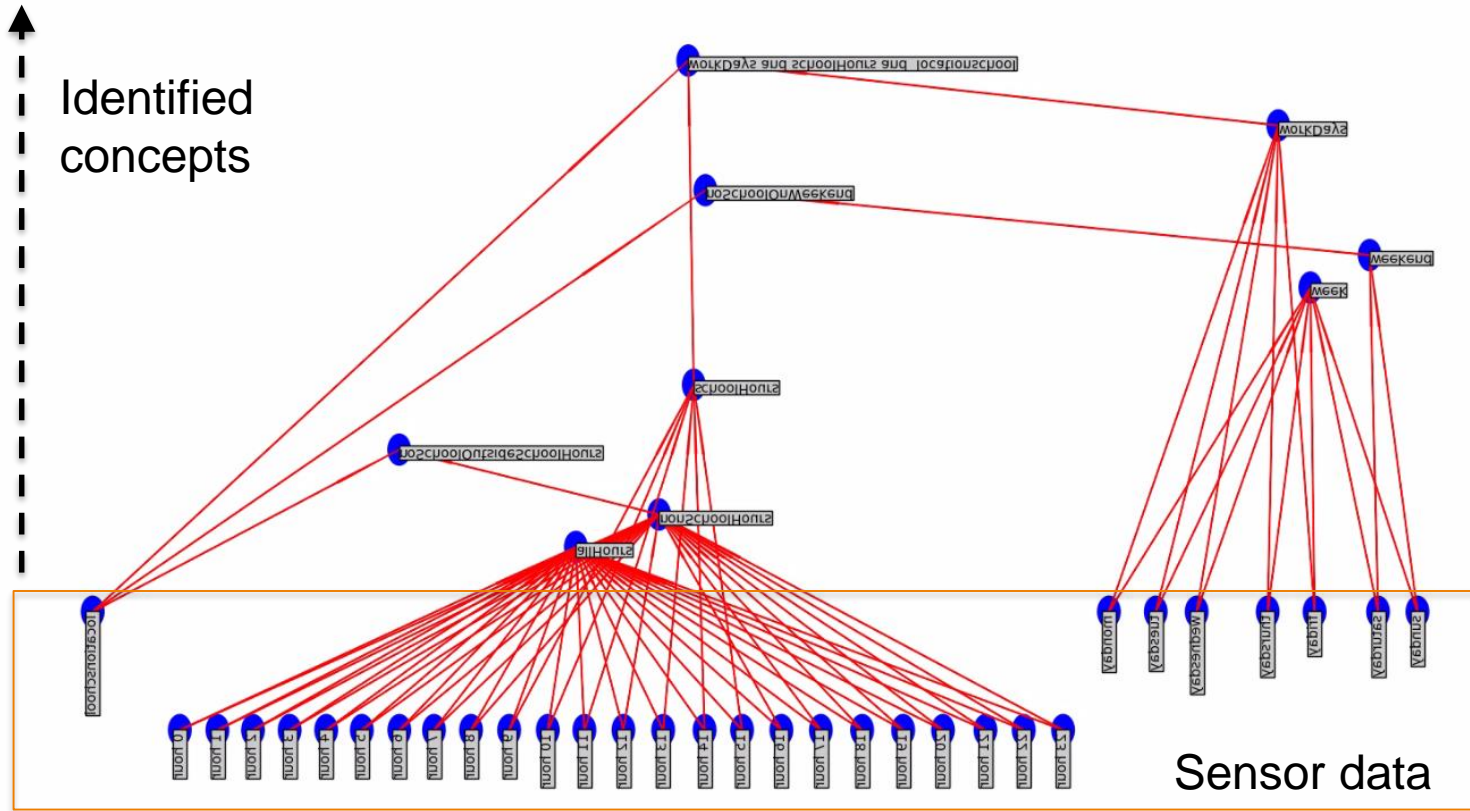

- › Too much data for human processing
- › Too little / uncertain data:
 - › combine with expert knowledge
- › False information

- › E.g. Neural Networks
- › And ... what about trust?

- › Neuro, Neural, sub-symbolic
 - › Information items have little or no meaning, e.g. pixels in an image
 - › Good at recognizing patterns, e.g. it is an image of a cat
 - › Typically requires a lot of data, no explainability
- › Symbolic
 - › Information items have meaning: concepts and relations
 - › Logic can be performed, explainable
 - › Typically requires human input such as rules
- › Neuro-symbolic
 - › Flexible network that requires reasonable data for training
 - › Using low level data but still have explainable results
 - › High level knowledge and corrections made by expert

- › Deriving pattern-of-life information from sensor data
- › Data without meaning (for the algorithm)
- › Patterns are derived automatically by searching for XOR, AND, etc.
- › Human adds meaning, i.e. the symbols

AUGMENT NEURAL WITH SYMBOLIC

Neighbourhood info:

- # households
- # cars per household

Rules, e.g.

- Factory -> Factory + low(# households)

Building info:

- Area
 - Shape
 - Distance to neighbour
- + actually identified buildings

House

Shop

Factory

Church

Villa

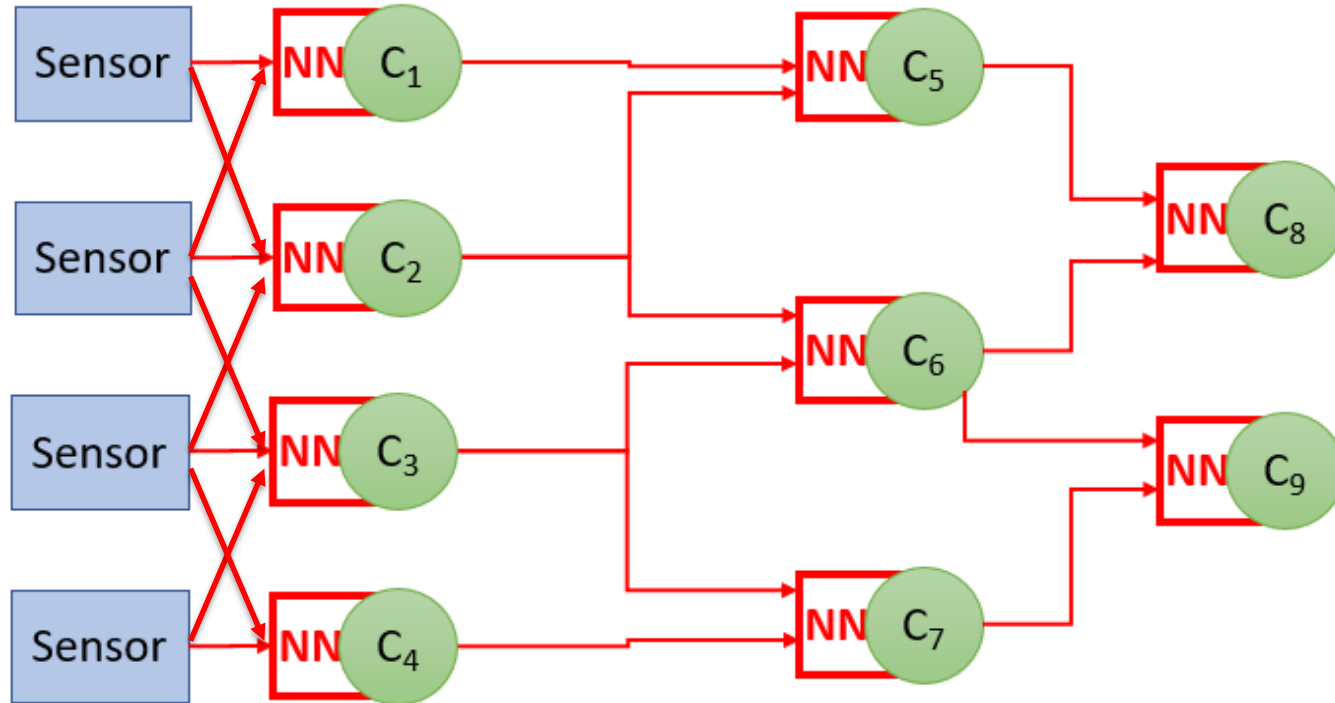

- › Neuro part (random forest) is hard to improve upon, even with little learning
- › Experts can express relations such as:

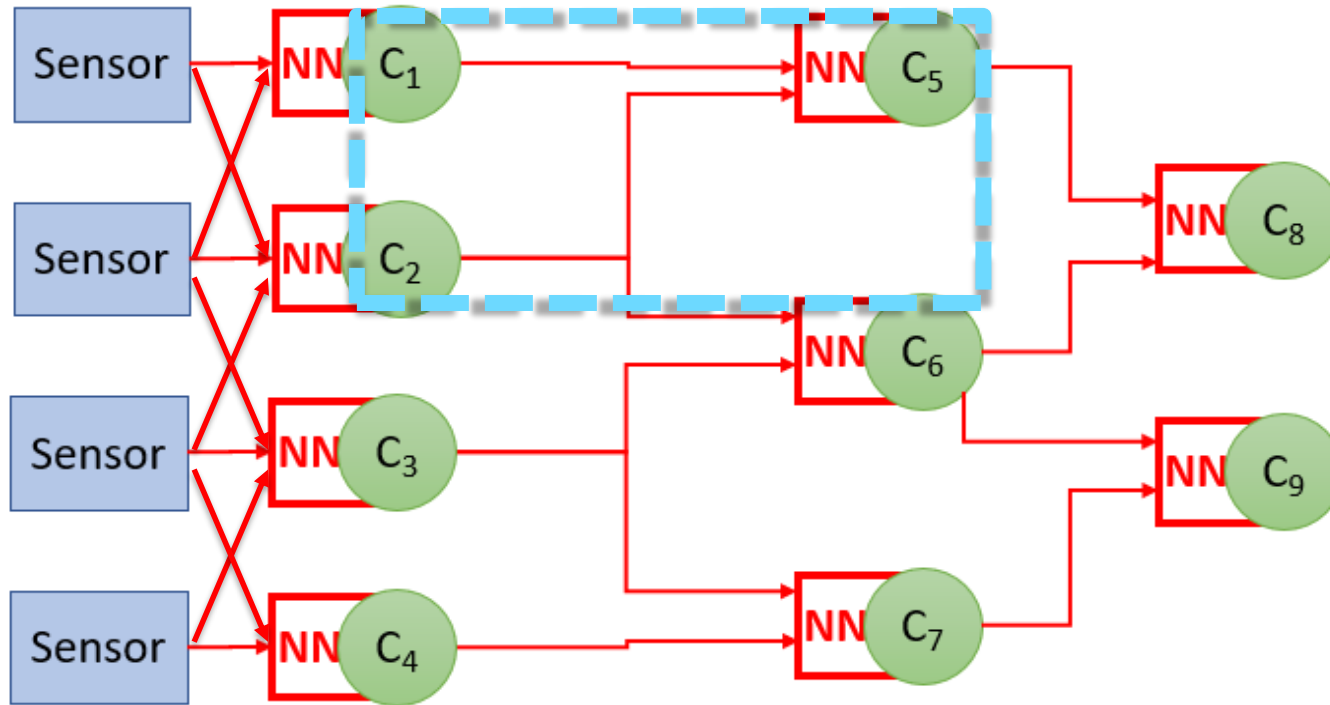

"Factory -> Factory + $\text{low}(\# \text{ households})$ "

- › But to improve upon the neuro part, experts would have to specify:

"Factory -> Factory + $0.21 * \text{low}(\# \text{ households})$ "

- › Explainability

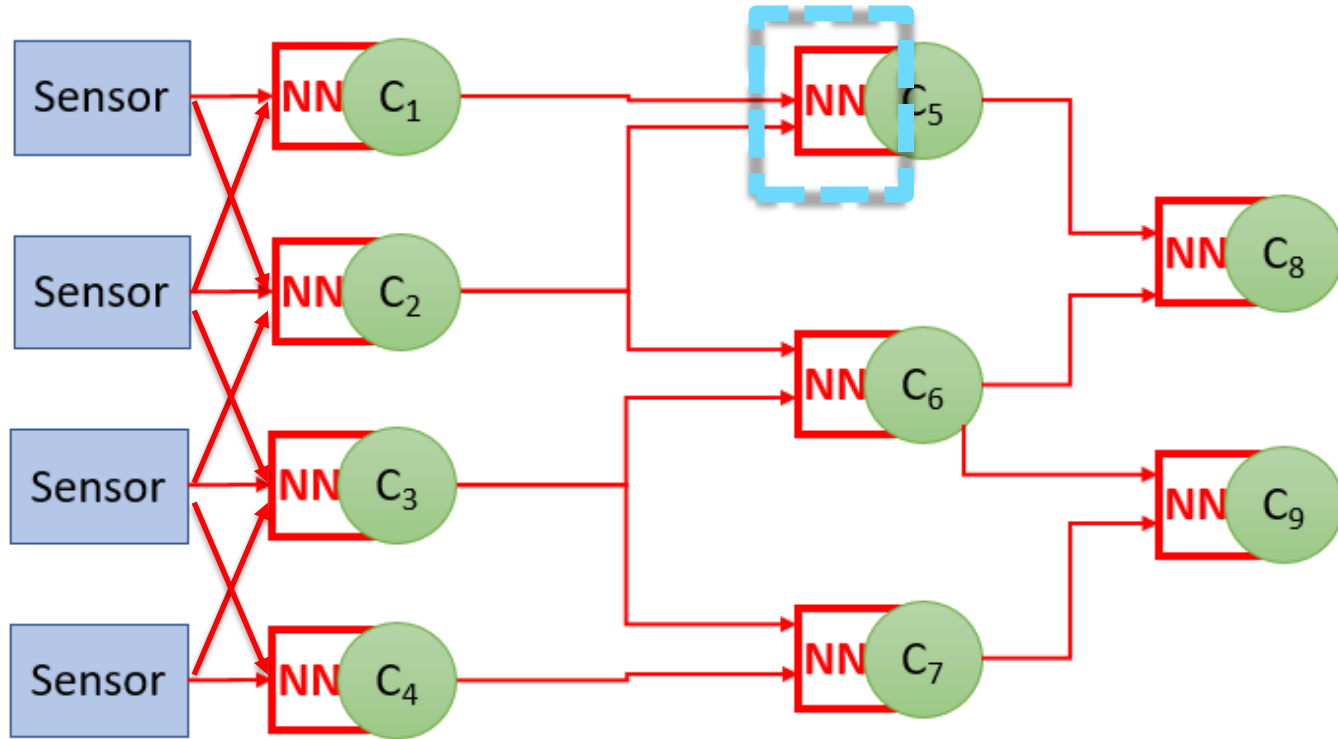

'Humane' relations

Different levels

- › By studying the resulting NN of a trained concept network we found
 - › Some concepts require only a simple NN,
 - › Other concepts require a more elaborate NN
 - › missing concepts? feedback to expert
 - › Links between concepts that are and are not useful
 - › feedback to expert, or automate addition/deletion of links
- › The results are - again - not as good as using a NN, but explainable!
- › Concept networks can with re-training be reused in other operations

- › Analysts and decision makers can be supported by simulation
- › Fit-for-purpose models have to be made/tailored during the operation
- › The combination of expert knowledge and AI can help determine what is and is not important in an explainable way

- › Several important technologies are being developed within NATO
 - › MSaaS, Datafarming
- › Neuro-Symbolic Modelling is a promising approach to combine low-level data with expert knowledge
 - › Cross-panel: Big Data and Artificial Intelligence for Military Decision Making

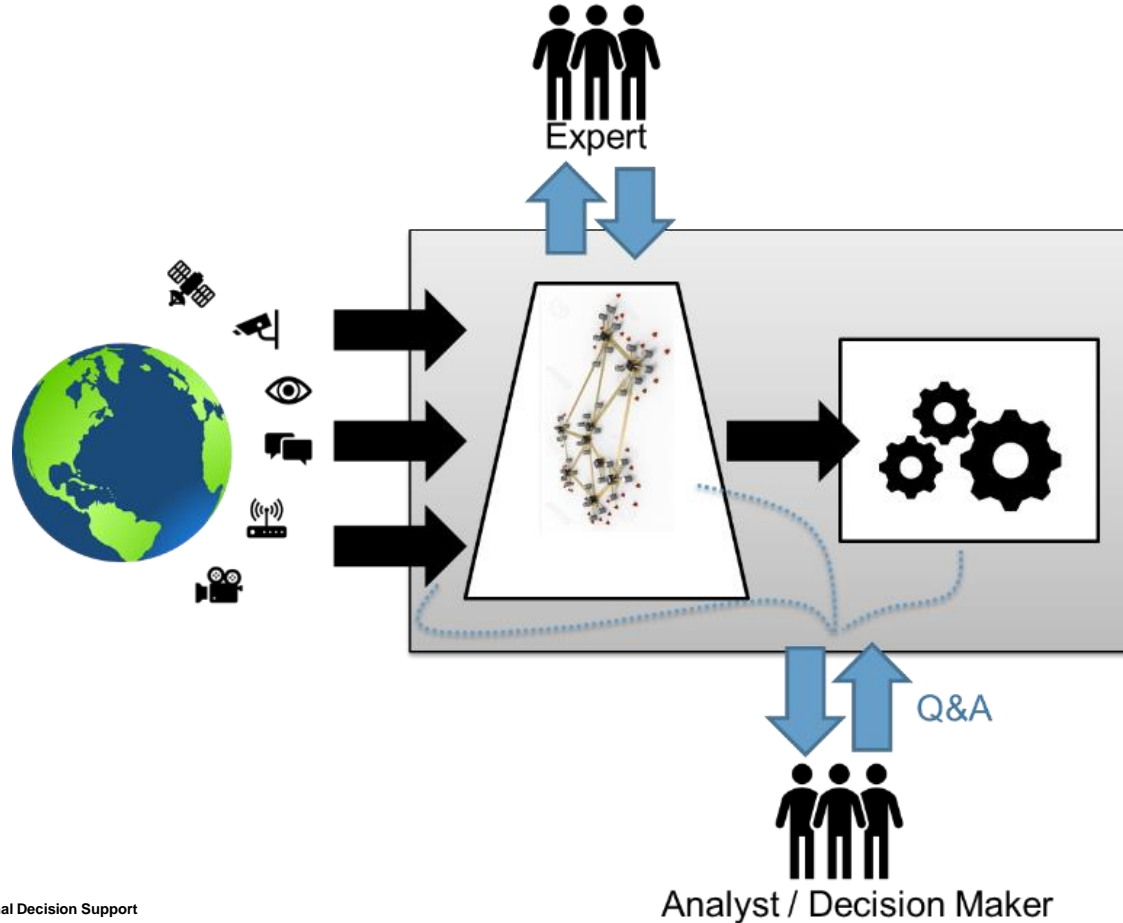

A nighttime photograph of a city street. In the foreground, a modern, curved pedestrian bridge with a glass railing is illuminated. The background shows a multi-story building with many lit windows and a street with light trails from moving vehicles. The overall scene is a mix of urban architecture and dynamic light effects.
