

Resilient Collaborative All-source **Navigation with Integrity SET-275 Cooperative Navigation in GNSS Degraded and Denied Environments** Maj Jonathon S. Gipson, PhD United States Dr. Robert C. Leishman, United States

#### Navigate "anytime, anywhere, using anything."

#### **All-Source Navigation**

With Global Navigation Satellite Systems, simultaneously redundant, synchronous measurements with provisions for integrity are readily available.

With all-source navigation, <u>none</u> of these are *guaranteed*.

#### Integrity

A *guarantee* of navigation accuracy which includes a timely, accurate estimate of navigation error with a mechanism to provide warnings when the estimate could be untrustworthy.

#### **All-Source Resilience**

The ability to maintain consistent all-source Fault Detection and Exclusion (FDE) and integrity operations. A *resilient* navigation framework is one that is "aware" of the sufficiency of sensor information to preserve this consistency if a sensor failure occurs. This research assumes a single simultaneous sensor failure.

#### Autonomous Resilient Management of All-source Sensors (2018) Jurado, Juan D., Raquet, John F., Schubert-Kabban, Christine M

#### Resilient All-source Framework with 5 modes:

- Offline/Failed
- Sensor Validation
- Monitoring (SAARM)
- Calibration
- Remodeling

ARMAS uses pluggable SCORPION EKFs to address the nonlinear navigation problem:  $\dot{\mathbf{x}}(t) = f[\mathbf{x}(t), \boldsymbol{\epsilon}(t), \boldsymbol{u}(t), t] + \boldsymbol{G}(t)\boldsymbol{w}(t)$ 

- State vector,  $\mathbf{x}(N \ge 1)$ , time,  $\mathbf{t}$
- State process model, *f(t)*, control input vector, *u(t)*,
- Sensor error states,  $\epsilon$  (*M* x 1)
- Linear noise operator,  $G(t)(N + M) \times W$
- White noise process, **w(t)** (W x 1)

Sensors are initialized as either trusted or untrusted.

### A unanimous agreement is required to determine a culprit.

# "Layer 2" Observability Subfilter Bank

### Goal: Monitor navigation resilience. Provide a timely warning when FDE and integrity assumptions are not guaranteed.

Subfilter Inheritance Axiom:

"If the estimation states of interest in all layer 2 subfilters are observable and stabilizable, then all layer 1 subfilters responsible for FDE and integrity operations inherit these properties." Solution: Assuming a single simultaneous sensor failure, one additional layer of subfilters is required to monitor resilience.

	Layer 0	Layer 1	Layer 2			
	User Output	Fault Detection & Exclusion	Stable Observability Monitoring			
	Single Main Filter	I 'choose' 1 Unique Filters	I 'choose' 2 Unique Filters			
	I sensors	I - $1$ sensors each	$I$ - $\mathcal 2$ sensors each			
igure: ARMAS Configuration with Novel Observability Bank						

Summary: Since a subset of the "Layer 2" observability subfilters will form the new "Layer 1" subfilter bank after fault exclusion, we provide a means to warn the user in the event that a future single sensor failure could jeopardize the consistency of the framework.

**Result: Timely warning to notify the user to augment with offboard information.** 5

### Stable Observability Monitoring (SOM) Overview

The ability to maintain stable a posteriori estimates of system states is a primary indicator of overall estimator stability (Ham 1983).

- If the system model is stochastically controllable and observable, then **P**<sup>+</sup> is **uniformly bounded from above**.
- Stabilizable states have a unique positive-definite P\*.

Monitor *aposteriori* state covariance element *n* across all observability subfilters with a moving window sized to ARMAS monitoring epoch.

Slope and Max Value Thresholds:

$$O_{k,i}(n) = \begin{cases} 1, & \text{if } \mathbf{P}_j^{[\mathbf{n}]}(t_k^+) > \mathbf{P}_j^{[\mathbf{n}]}(t_{k-M}^+)\beta \\ 1, & \mathbf{P}_j^{[\mathbf{n}]}(t_k^+) > \mathbf{P}_{j,max} \\ 0, & \text{otherwise} \end{cases}$$

**Relationship between Information Filter vs Kalman Filter** Discrete Recursive Fisher Information Filter:

 $\boldsymbol{F}(t_k^+) = \boldsymbol{\Phi}^T(t_k)\boldsymbol{F}(t_k^-)\boldsymbol{\Phi}(t_k) + \mathbf{H}^T(t_k)\mathbf{R}(t_k)^{-1}\mathbf{H}(t_k)$ 

Recursive Inverse Covariance Kalman Filter:

 $\mathbf{P}(t_k^+)^{-1} = \mathbf{P}(t_k^-)^{-1} + \mathbf{H}^T(t_k)\mathbf{R}(t_k)^{-1}\mathbf{H}(t_k).$ 

User sets  $\mathbf{P}_{j,max}$  as a maximum static  $P(t_k^+)^{[n]}$  allowable. User sets  $\boldsymbol{\beta}$  as a tuning parameter for acceptable transient  $P(t_k^+)^{[n]}$  growth allowable.

$$SOM_{AddNewSensor} = \begin{cases} true, & \text{if } \sum_{n=1}^{N} O_k(n) > 0\\ false, & \text{otherwise} \end{cases}$$

If <u>any</u> observability layer subfilter exceeds the <u>slope</u> or <u>max value</u> threshold, *warn* user to *augment* with offboard information.

SOM monitors the stability of *aposteriori* system state estimates in the observability layer to provide an assessment of the signal/noise ratio supplied to system states.
